Abstract

Wing-collection and singing-ground surveys of woodcock (*Philohela minor*), which are conducted rangewide in the United States annually, were compared to identify changes in harvest, age ratios in the harvest, hunting activity, and breeding population indices between 1974-75 and 1975-76. During 1975-76 the productivity index decreased 13% rangewide, 10% in the Atlantic Region, and 16% in the Central Region. Rangewide, the daily hunting success index decreased 3%, whereas the seasonal hunting success index decreased 1%. Daily hunting success indices decreased 3% in each region, whereas the seasonal hunting success index increased 6% in the Central Region and decreased 6% in the Atlantic Region. The breeding index increased 3% rangewide, decreased 2% in the Atlantic Region, and increased 6% in the Central Region.

During the past decade American woodcock (*Philohela minor*) have become an increasingly popular game bird over most of their U.S. range (Fig. 1). State and Federal surveys show that the number of woodcock hunters is increasing. Thus, woodcock have advanced from a "speciality" game bird, sought by a few ardent hunters, to a broader-based recreational resource pursued by many sportsmen. Owen (1976) estimated that woodcock provide between 2.5 and 3.0 million man-days of hunting in the United States annually.

No suitable sampling framework is available to determine total annual woodcock harvest by all U.S. woodcock hunters. Presently, woodcock harvest estimates are made by adjusting hunter responses from the U.S. Fish and Wildlife Service's waterfowl hunter questionnaire. Clark (1972) asserted that harvest estimates determined from the Service's waterfowl hunter questionnaire were less than 50% of estimates determined from State surveys. Therefore, he believed that doubling the woodcock harvest of waterfowl hunters would provide a conservative estimate of U.S. woodcock harvest. If Clark's assertion is correct, an average of 1.5 million

woodcock were harvested during the 1974-75 and 1975-76 hunting seasons. This figure represents a 79% increase from the average of the 1964-65 and 1965-66 seasons (Table 1).

In Canada, all migratory game bird hunters are required to obtain Federal permits. Thus, in recent years their sampling methods have allowed woodcock harvest to be measured more accurately than in the United States. In 1975, 131,000 woodcock were harvested in Canada (Dobell 1976). Combining Canadian and U.S. harvest estimates indicates that the continental woodcock harvest exceeded 1.6 million birds during the 1975-76 hunting season.

Presently, two surveys, the wing-collection survey and the singing-ground survey, provide the best information available for establishing annual woodcock hunting regulations in the United States. The Service's woodcock wing-collection survey provides estimates of reproductive success during the previous breeding season, hunter success, and changes in size and distribution of the harvest. The cooperative U.S. and Canadian singing-ground survey provides an index to the size of the breeding population on principal breeding areas. This report presents data from the 1975-76 wing-collection survey, the 1976 singing-ground survey, and additional information accumulated since publication of the 1975 status report (Artmann 1977).

Present address: U.S. Fish and Wildlife Service, Federal Assistance, P.O. Box 25486, Federal Center, Denver, CO 80225.

Wing-Collection Survey

Procedures

Procedures for collecting, processing, and analyzing wing-collection survey data have been described by Clark (1970, 1973). Survey participants were selected in a nonrandom manner from the following sources: (1) survey participants from the previous year; (2) woodcock hunters who responded to the Service's waterfowl hunter questionnaire or State harvest surveys; and (3) those who requested to be included in the survey. Clark (1972) discussed biases associated with selecting a survey sample from these sources; however, he asserted that major changes in productivity and hunting success could be determined from such a sample. For many analyses, only data from comparable hunters (hunters who have participated in the survey for two consecutive years) have been used. Some data also have been weighted to reflect differences in the number of participants and size of the harvest in various States (Clark 1970). Wing totals vary between tables in this report because incomplete information necessitated exclusion of some wings from various tabulations.

^a Average of the two latest hunting seasons for which data are available (final 1974-75 and preliminary 1975-76).

^b Increase from the average of 1964-65 and 1965-66 hunting seasons.

Results

During the 1975-76 wing-collection survey, 9,130 woodcock hunters were contacted. Twenty-three percent responded and furnished data from one or more hunts. Wings were submitted from 21,440 woodcock. Hunter response rates have been consistently higher in northern States than in southern States (Table 2). To compensate for this difference and to improve the distribution of the wing sample, more hunters in mid-latitude and southern States have been contacted in recent years (Table 3). A State-by-State comparison of the number of cooperators, envelopes, and wings received during the 1974-75 hunting seasons is shown in Table 4.

Productivity Index

The ratio of immatures per adult female in the wing survey is used as an index to reproductive success during the preceding breeding season. Considerable variation in age ratios occurred among harvest areas (Table 5) and between hunting seasons for the same harvest areas (Table 6). In addition to sampling variance, variation may be caused by differences in hunting season dates, weather conditions, hunting restrictions, and possibly a combination of differential migration and hunting vulnerability. In an

attempt to reduce some of this variation, only data from comparable hunters have been used in computing the weighted age ratios.

The 1975-76 rangewide productivity index decreased 13% from the 1974-75 index and 8% from the 11-year average (Table 6, Fig. 2). Generally, age ratios were lower across the northern tier of States (Fig. 3).

Separating the 1975-76 rangewide age ratio data into Regional components suggested that productivity decreased 10% in the Atlantic Region and 16% in the Central Region. Comparing Regional data from 1965 to 1975 revealed no significant trends in productivity. In both Regions the 1975-76 productivity index was below the long-term average; 2% in the Atlantic Region and 13% in the Central Region (Fig. 4).

Hunting Success Index

Based on rangewide data from comparable hunters, the daily hunting success index (average number of wings per envelope) decreased 3% between the 1974-75 and 1975-76 hunting season, whereas the seasonal hunting success index (average number of wings per cooperator) remained essentially constant (-1%; Table 7). Rangewide, daily hunting success

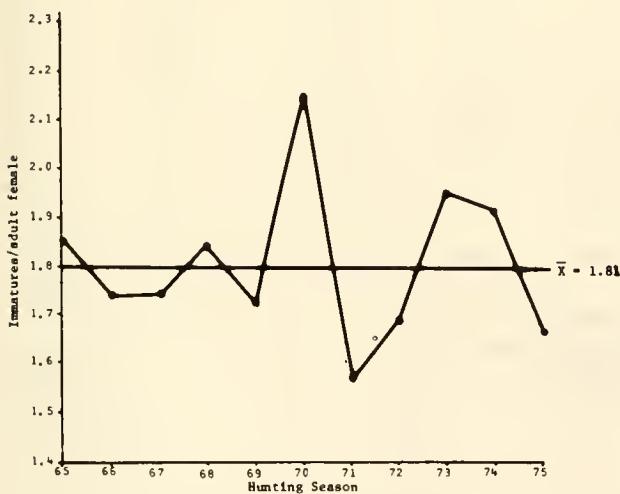

Fig. 2. Rangewide weighted age ratio indices (adjusted to base year 1969-70) determined from annual woodcock wing collections. Only data from cooperators who participated in the survey for 2 consecutive years were used.

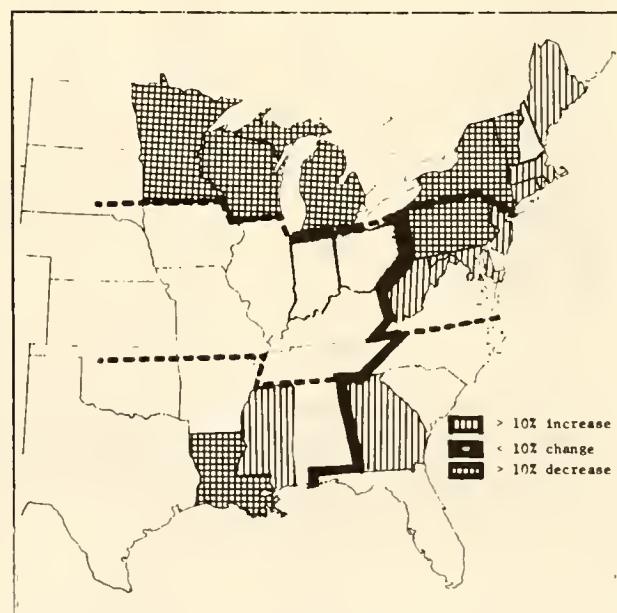

Fig. 3. Percentage change in weighted age ratios as determined from wing-collection data from cooperators who participated in both the 1974-75 and 1975-76 surveys.

Code 9 - From a list provided by a State.

indices from 1965-75 showed a significant downward trend ($r = -0.59$), whereas seasonal hunting success for the same period does not have a significant trend (Fig. 5). However, seasonal data from 1967-75 indicated a downward trend. The reason for these declines is not known, but it probably is because of the expansion in the number of hunter contacts in mid-latitude and southern areas in recent years (Table 3). These hunters are generally less successful and their success varies widely between years, depending on the influence of weather on migration patterns.

Regional separation of 1975-76 daily hunting success data indicated lower (about 3%) indices in both Regions (Fig. 6). These indices were about 5% below the 1965-75 average and have significant downward trends. Although the 1975-76 seasonal hunting success index in the Atlantic Region decreased approximately 6%, it increased approximately 6% in the Central Region (Fig. 6). No statistically significant trends were indicated in either Region. However, since 1967 the Atlantic Region's seasonal hunting index has decreased; the 1975-76 index was 12% below the 1965-75 average. In contrast, the Central Region's index has increased since 1970 and the 1975-76 index was 7% above the previous 7-year average.

Another measure of hunting success was the size

and distribution of daily bag information submitted by hunters. During the 1975-76 season, the percentage of hunts with daily bags larger than the 1971-75 season average was higher (Table 8). The north-central harvest area (Fig. 1) had the greatest percentage increase in the bag size of 5. In contrast, the mid-central harvest area had a slight decrease in larger daily bags and a corresponding increase in smaller bag sizes.

Chronology of Harvest

States with large wing samples provide indications of harvest and migration chronology. Data were summarized by 7-day periods, beginning with the opening hunting season date in each State from 1972-73 to 1975-76 (Tables 9 and 10). Hunter harvest varies even though the opening date is essentially the same, reflecting the influence of weather on migration, time of leaf fall, and hunter activity. However, when a large proportion of the harvest consistently occurs at the beginning or end of the hunting season, it indicates that hunting season dates could be adjusted accordingly to maximize hunting opportunity. In those States represented by small wing samples, information from other States at the same general latitude can be used to approximate the migration period.

Singing-Ground Survey

Procedures

The spring singing-ground survey, which involves counts of displaying males heard along pre-determined routes, is interpreted as an index to the size of an area's resident breeding woodcock population. Before 1964, "management routes" were established in areas known to support woodcock. From 1964 to 1970, the survey was shifted gradually to routes located randomly throughout the major breeding range. Since 1970, the breeding population index has been based solely on "random routes," which provide better statistical reliability. In computing the breeding index, data from States and Provinces were weighted by land area (inland water area excluded) within the range of the species (Clark 1970).

Routes where woodcock have not been heard for two consecutive years, under similar circumstances, are placed in the "Constant O" group. They are included in comparable route calculations annually, but are field-checked only at 5-year intervals until woodcock are heard again.

Since paired routes may not be the same in consecutive years it is meaningless to present

numbers of singing birds heard per route. Similarly, conversion to random routes, which have averaged fewer birds than management routes, also precludes comparing the average number of birds heard per route. In order to compare the results, the data were adjusted by the percentage change in numbers of birds heard between years, with 1970 as the base year (Clark 1973).

Results

During 1976, the number of woodcock heard rangewide along 954 comparable routes increased 2.8% (Table 11). Separating the data into Regional components showed that the Atlantic Region breeding population index (BPI) decreased 1.5%, while the Central Region's increased 5.8% (Fig. 7). The decrease in the Atlantic Region's BPI continued the general decrease apparent since 1967; the 1976 index was 14% below the 1964-76 average (Fig. 8). A regression model indicated an annual rate of decrease of 2% per year in the Atlantic Region ($P < 0.01$). In contrast, the Central Region's BPI decreased before 1969, but since then has exhibited a general upward trend ($P < 0.05$); the 1976 index was about 15% above the 1964-76 average.

Relative woodcock densities are shown by geographical area in Fig. 9. Highest densities were

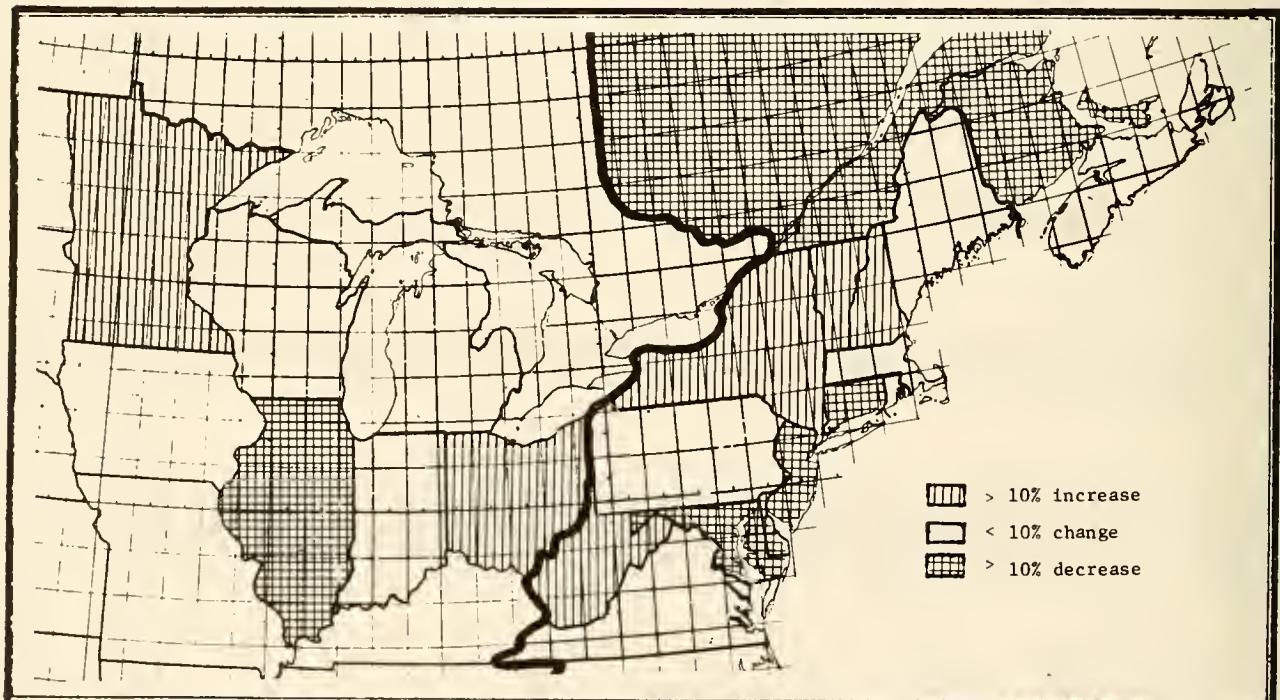

Fig. 7. Percentage change in woodcock breeding population indices as indicated by the singing-ground surveys in 1975 and 1976.

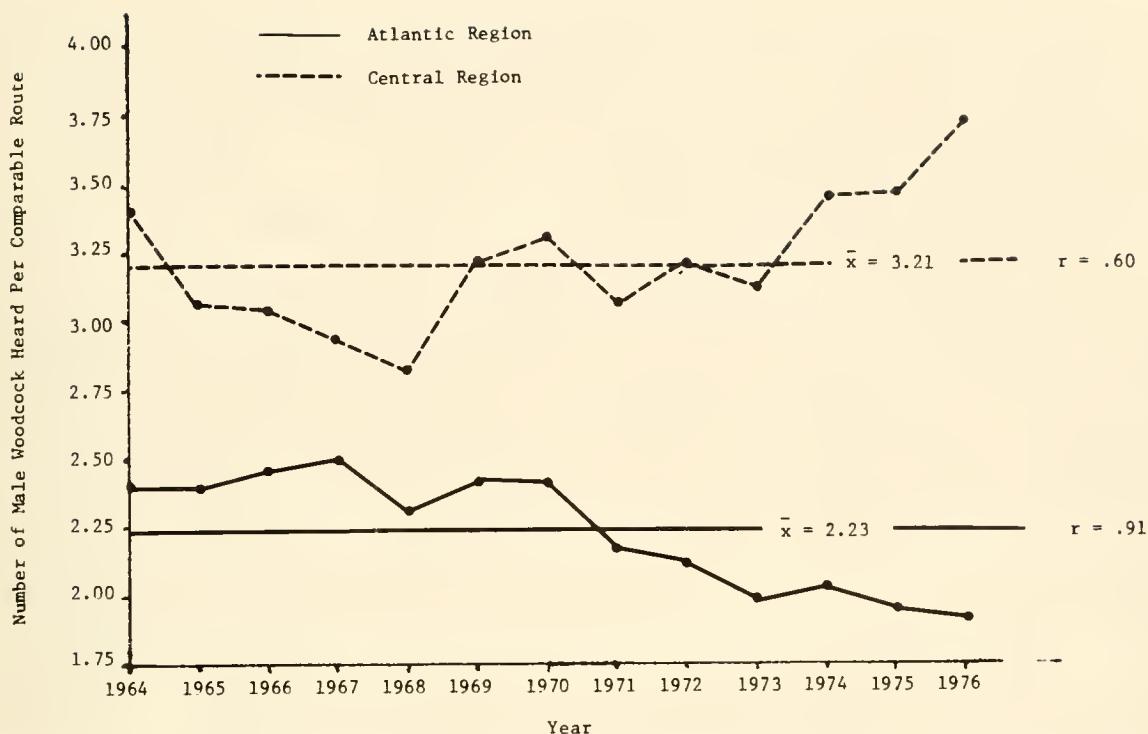

Fig. 8. Regional trends in the woodcock breeding population index as determined by singing-ground surveys. Data adjusted to base year 1970.

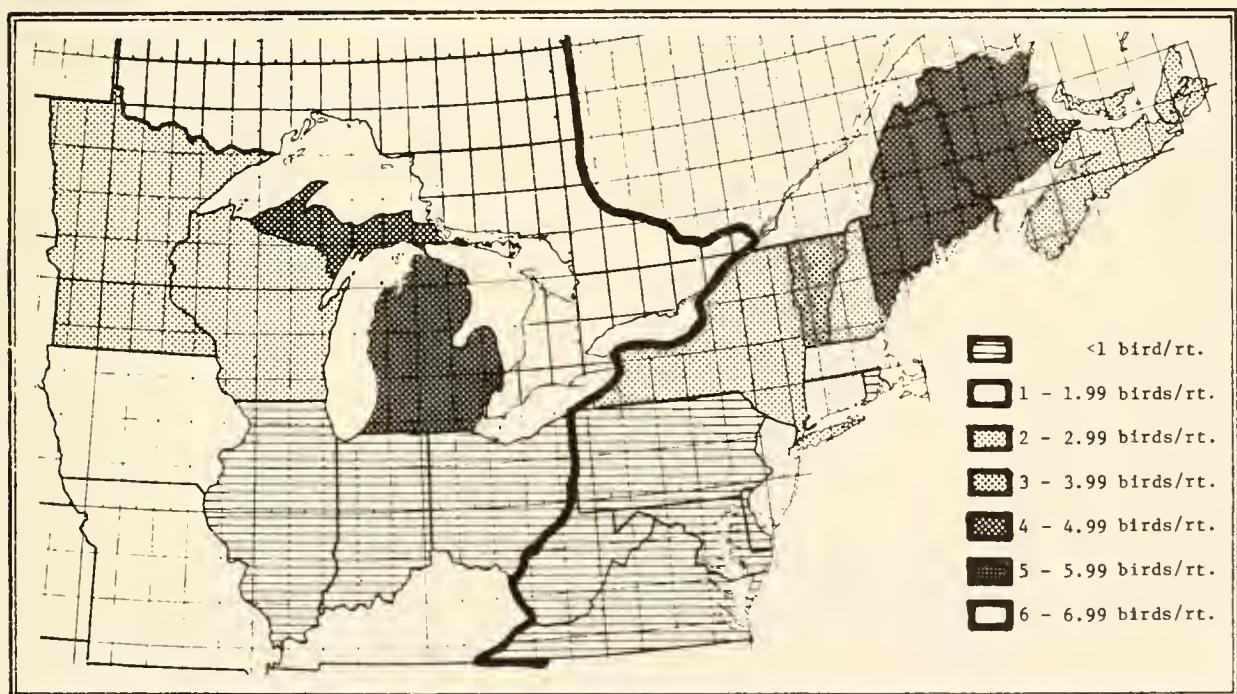

Fig. 9. Relative woodcock densities as determined by the 1976 singing-ground survey.

Table 11. *Woodcock breeding population indexes as indicated by singing-ground surveys in 1975 and 1976 (random routes only).*

State or Province	Number of routes censused		Comparable routes ^a	Woodcock heard per comparable route	
	1975	1976		1975	1976
Atlantic Region

Regional index change					+5.82%
Rangewide total & weighted average ^b	870	923	954	2.69	2.77
Rangewide index change					+2.78%

^aIncludes routes carried as constant zero routes.

^bWeighted averages are sums of products of woodcock heard per comparable route and the corresponding State or Province percentage of the total land area sampled. States or Provinces excluded where one comparable route represents more than 5,180 km² (2,000 square miles) or where the number heard per route is less than 0.5.

recorded in the northern States and southern portions of the Provinces. Generally, areas south of 42° latitude had fewer than one woodcock heard per route.

Acknowledgments

Most data in this report would not be available without the cooperation of the Canadian Wildlife Service, Provincial and State conservation departments, U.S. Fish and Wildlife Service personnel of Regions 3, 4, and 5, and the many individuals who assisted in the surveys. Special recognition is extended to K. Munson for help in preparing the report, R. Hines for the cover sketch, and T. Dwyer, R. Pospahala, and L. Schroeder for reviewing the manuscript.

Special thanks are extended to the biologists who helped process nearly 22,000 woodcock wings. These cooperators and the affiliations are as follows:

G. Carowan	U.S. Fish and Wildlife Service
P. Corr	Maine Department of Inland Fisheries and Game
W. Cottrell	Maryland Department of Natural Resources
K. D'Loughy	Maryland Department of Natural Resources
B. Dorf	Maryland Department of Natural Resources
G. Gard	U.S. Fish and Wildlife Service
D. Langowski	U.S. Fish and Wildlife Service
B. Larned	Maryland Department of Natural Resources
T. Mathews	Maryland Department of Natural Resources

R. McKee	Maryland Department of Natural Resources
C. Mohlis	U.S. Fish and Wildlife Service
C. Nicholson	University of Maine
H. R. Perry, Jr.	U.S. Fish and Wildlife Service
T. Prickett	Louisiana Wildlife and Fisheries Commission
M. Rubala	Maryland Department of Natural Resources
F. Simms	U.S. Fish and Wildlife Service
B. Sondericker	Maryland Department of Natural Resources
S. Stenquist	U.S. Fish and Wildlife Service
A. Talbott	Hocking Technical College
W. H. Taylor	Virginia Commission of Game and Inland Fisheries
S. Yarsa	Ohio State University

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in island territories under U.S. administration.
